Nuclear Energy Expansion and Labor Dynamics in the U.S. Utilities Sector

A Data-Driven Policy Brief

Dwanjai Oprien

March 20, 2026

Executive Summary

This brief examines the relationship between nuclear electricity production and employment in the U.S. utilities sector using time-series data from the Federal Reserve Economic Data (FRED).

The analysis finds that while nuclear energy production expanded significantly during the late 20th century, employment in the utilities sector did not grow proportionally. Instead, employment peaked in the early 1990s and declined thereafter, even as production levels remained high.

These findings suggest that nuclear energy systems transition from labor-intensive development phases to capital-intensive operational phases, with important implications for workforce planning, infrastructure investment, and long-term energy policy.

Background

Energy infrastructure development has historically played a central role in shaping labor demand within the utilities sector. During periods of rapid expansion, such as the nuclear buildout of the late 20th century, large-scale construction and deployment require substantial labor inputs.

However, as infrastructure matures, the relationship between production and employment may shift. Understanding this transition is critical for policymakers, particularly as new investments in energy systems—including nuclear, renewable, and grid modernization—continue to expand.

Data and Methodology

This analysis uses publicly available time-series data from the Federal Reserve Economic Data (FRED) database:

- Industrial Production: Nuclear Electric Power Generation (IPN221113N)
- All Employees: Utilities (CES4422000001)

The study employs:

- Time-series trend analysis

- 12-month moving averages to smooth employment fluctuations
- Indexed comparisons (base year = 100) to evaluate relative growth

These methods allow for a comparative assessment of long-term structural relationships between energy production and labor demand.

Key Findings

The results indicate a clear transition in the utilities sector from a labor-intensive development phase to a capital-intensive stabilization phase.

Figure 1 shows that utilities employment increased steadily from the late 1970s through the early 1990s, reflecting large-scale infrastructure expansion and system development.

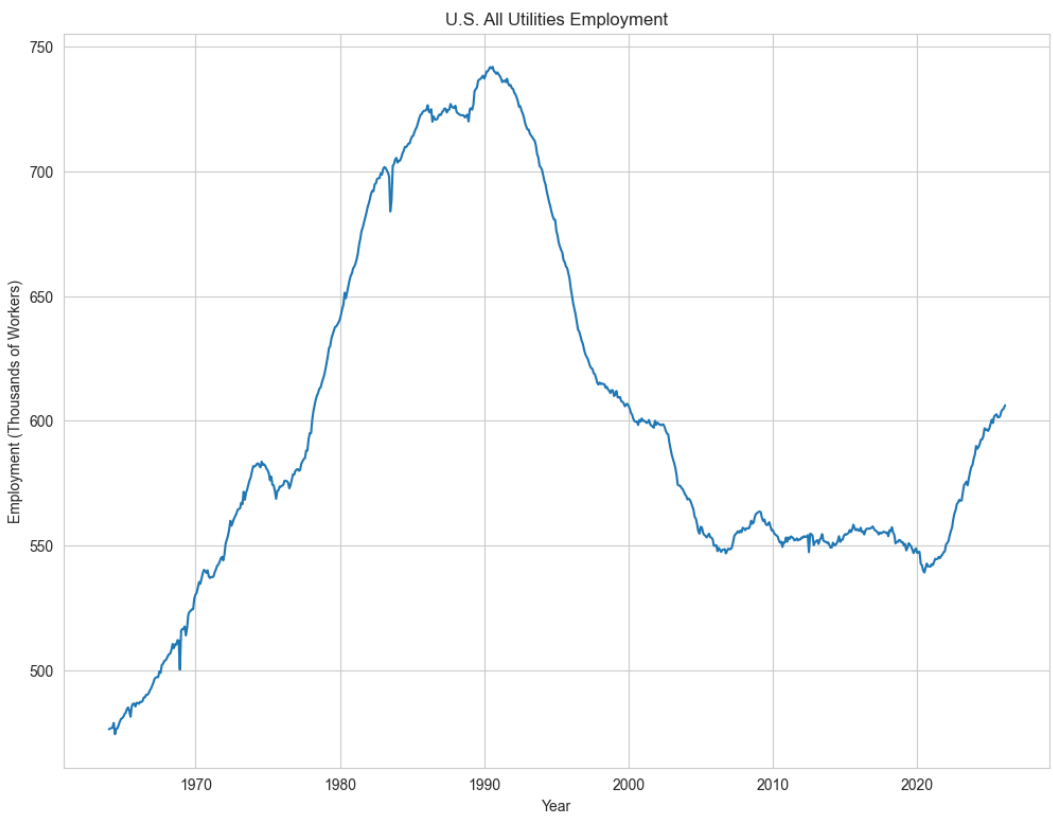

Figure 1: U.S. All Utilities Employment (Thousands of Workers)

This period corresponds to a construction-intensive phase in which labor demand was high.

To better understand long-term trends, **Figure 2** presents a smoothed version of utilities employment using a 12-month moving average.

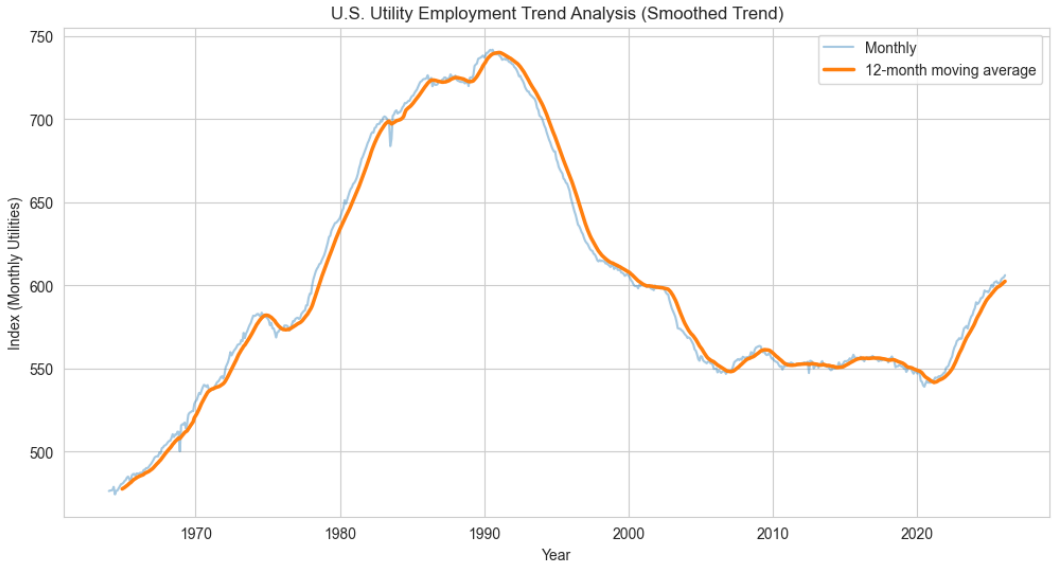

Figure 2: Smoothed Utilities Employment Trend (12-Month Moving Average)

The smoothed trend highlights a clear peak in the early 1990s followed by a sustained decline, indicating a shift away from expansionary labor demand as infrastructure matured.

Figure 3 compares indexed nuclear electricity generation and utilities employment over time.

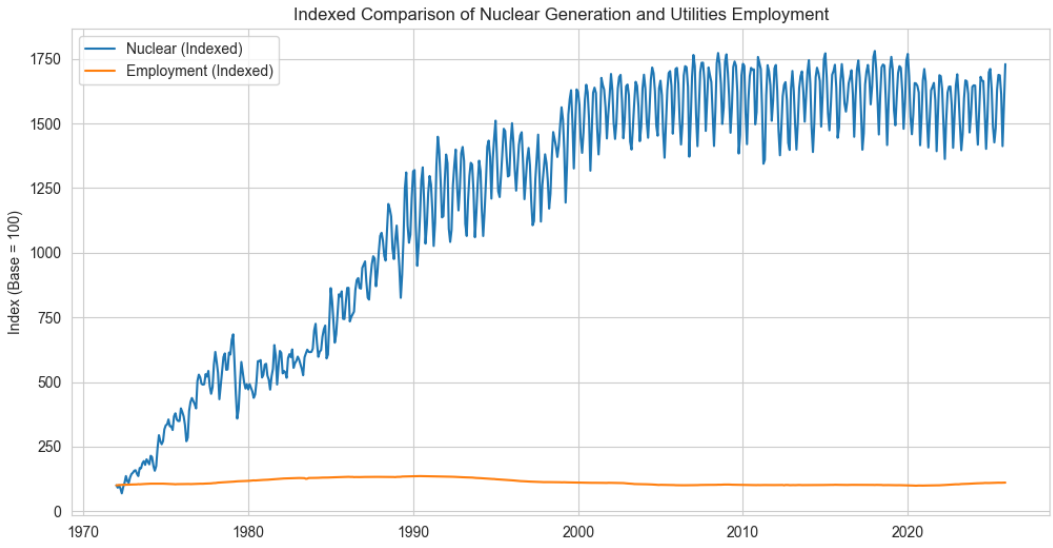

Figure 3: Indexed Comparison of Nuclear Generation and Utilities Employment (Base = 100)

While nuclear generation increased substantially and later stabilized at high output levels, utilities employment remained relatively flat or declined.

This divergence suggests that nuclear energy production is not labor-proportional in the long run. Instead, output growth appears to be driven by capital investment, technological improvements,

and operational efficiencies rather than workforce expansion.

Although a modest recovery in employment is observed following the COVID-19 pandemic, the available data does not support a definitive structural shift in labor demand.

Policy Implications

As investment in energy infrastructure expands, policymakers must account for the evolving relationship between production and labor demand.

While early-stage development is labor-intensive, the long-term operation of nuclear energy systems is increasingly capital-intensive, with limited proportional growth in employment. This has important implications for workforce planning, as future investments may not generate broad-based job growth in the utilities sector.

Instead, policy efforts may need to focus on:

- Workforce specialization and technical training
- Efficient allocation of capital resources
- Long-term operational sustainability rather than short-term employment expansion

Understanding this shift is critical for aligning energy investment strategies with realistic labor market expectations.

Conclusion

The U.S. utilities sector demonstrates a clear transition from labor-intensive growth during infrastructure expansion to a more capital-intensive and efficiency-driven model.

As nuclear energy production stabilized at high output levels, employment did not scale proportionally, highlighting the importance of distinguishing between development-phase and operational-phase labor dynamics.

These findings provide a foundation for future research on energy labor markets and offer important considerations for policymakers navigating the next generation of energy investments.
